WHAT IT IS, SIMPLY

Most messages are from people who are annoyed but staying.

Customer care teams get thousands of messages: WhatsApp, X, Hellopeter. A few of them come from people who are quietly leaving. Those few look almost identical to the rest, so they get answered in the order they arrive, which is the worst possible order.

WHAT IT DOES

Three questions. One queue.

You paste a message and it answers: is this person about to leave, how fast must you reply, and what is it about?

LEAVING?

churn intent

HOW FAST?

urgency

ABOUT WHAT?

topic

Respond Now · Today · This Week · Monitor

The person working the queue knows who to phone first.

WHY IT IS DIFFERENT FROM SENTIMENT ANALYSIS

Anger is not intent.

Sentiment tells you a message is negative. That is useless on its own, because most messages are negative. This tells you intent.

ANGRY, BUT STAYING

“This is unacceptable.”

ACTUALLY LEAVING

“This is my last month with you.”

My old project scored the first one and missed the second.

DO THE NUMBERS HOLD?

90%

F1, spots a leaver

keyword rule: 50%

74.5%

of leavers reached

answering top 20%

18%

if you work top to bottom

the old way

On 819 messages the model never saw, it caught leavers with 90% F1, against 50% for a simple keyword rule. The number that matters to a manager: if you can only answer 20% of your inbox, this picks the right 20% often enough to reach 74.5% of the people who were actually leaving.

WHAT IS NOT PROVEN

Synthetic data.
Real accuracy will be lower.

Those numbers show the method works, not that it will hit 90% on real customers. The data is synthetic, built from themes in public complaints rather than from anyone's actual messages.

That is the first thing I say, not the last.
